

Referee 1 – Comments to the revised paper

The paper is focused on a numerical method to assess tower base loads and low-frequency noise emissions of wind turbines. The computational setups is clearly described and the result are well presented confirming the credibility of the work and its relevance in the field.

The reviewer noticed that all the requested “minor revisions” were fulfilled by the authors by correctly answer the reviewer’s questions and adding further explanation in the paper. So, the paper can be considered acceptable as is.

Concerning the last reviewer’s request about the “acoustic immission” definition, the reviewer got the point (thanks for the clear explanation), so the use of this archaic English adjective seems to be fully justified.

Finally the reviewer noticed that in the “version 2” of the paper, some inconsistencies seem to be present in the data included in Fig. 9, 10 and 14 (there inconsistencies were not present in the previous version). Please be careful when submitting the final version.
